## Conclusions

# Context

## Host-based botnet detection

- ▶ The **bot** need communicate with the bot-master:
  - ▶ receives special commands: does **malicious** things,
  - ▶ otherwise: stays **inactive**.
- ▶ In general: **trigger-based malwares**.

## Real-life infamous examples

- ▶ **Stuxnet**: "... checks the value NTVDM TRACE... If this value is equal to... infection will not occur..." Falliere et al. 2011
- ▶ **Gauss**: "... decrypt... the payload using several strings from the system and, upon success, executes it... " GReAT 2013

# Researches on the code coverage

## Code coverage is considered

- ▶ **extensively** on the source code of programs (Godefroid et al. 2005 and numerous subsequent works).
- ▶ but **much fewer** if one considers
  - ▶ binary codes,
  - ▶ malicious obfuscated programs(Moser et al. 2007 and Brumley et al. 2008).

## Detecting trigger-based malwares

- ▶ The direct dynamic-analysis fails (limited behaviors).
- ▶ The static-analysis faces some difficulties:
  - ▶ few work on the binary codes,
  - ▶ very sensitive to the **obfuscation** (Moser et al. 2007).
- ▶ We propose a **hybrid approach**.

Conclusions

# Trace covering: hidden behaviors detection

**Hybrid approach:** execute a program  $P$  which receives an input message  $m$ , we get a **trace**  $t$ .

as a sequence of instructions

```
...
0x40096b: mov cl, al
0x40096d: mov byte ptr [rbp-17], cl
0x400970: movsx eax, byte ptr [rbp-17]
0x400974: sar eax, 4
0x400977: cmp eax, 5
0x40097c: jle 0x4009af
0x40099b: call 0x400860
0x400860: ....
```

```
0x4009af: call 0x4008c0
0x4008c0: ...
```

as a path on the CFG

# Trace covering: hidden behaviors detection

**Hybrid approach:** execute a program  $P$  which receives an input message  $m$ , we get a **trace**  $t$ . For each **conditional branch**  $br \in t$ ,

as a sequence of instructions

```
...
0x40096b: mov cl, al
0x40096d: mov byte ptr [rbp-17], cl
0x400970: movsx eax, byte ptr [rbp-17]
0x400974: sar eax, 4
0x400977: cmp eax, 5
0x40097c: jle 0x4009af
0x40099b: call 0x400860
0x400860: ....
```

```
0x4009af: call 0x4008c0
0x4008c0: ...
```

as a path on the CFG

# Trace covering: hidden behaviors detection

**Hybrid approach:** execute a program  $P$  which receives an input message  $m$ , we get a **trace**  $t$ . For each **conditional branch**  $br \in t$ , find  $m'$  so that the execution of  $P$  leads to a new **trace**  $t'$

as a sequence of instructions

```
...
0x40096b: mov cl, al
0x40096d: mov byte ptr [rbp-17], cl
0x400970: movsx eax, byte ptr [rbp-17]
0x400974: sar eax, 4
0x400977: cmp eax, 5
0x40097c: jle 0x4009af
0x4009af: call 0x4008c0
0x4008c0: ...
```

as a path on the CFG

Conclusions

# Backtracking on the CFG of the program

Main ideas: for each checkpoint  $br \in t$ :

- ▶ **fuzz testing minimization**: find the minimal parts  $I_{br} \subseteq m$  of the input message affecting  $br$ 's decision,
- ▶ **re-execution trace optimization**: find the nearest execution checkpoints  $C_{br} \in t$  affecting  $br$ 's decision.

# Backtracking on the CFG of the program

Main ideas: for each checkpoint  $br \in t$ :

- ▶ **re-execution trace optimization**: find the nearest execution checkpoints  $C_{br} \in t$  affecting  $br$ 's decision.

...let's consider an example

## Example (program)

```
0x400966: call 0x4006e0 ;get_msg
0x40096b: mov cl, al
0x40096d: mov byte ptr [rbp-17], cl
0x400970: movsx eax, byte ptr [rbp-17]
0x400974: sar eax, 4
0x400977: cmp eax, 5 ;x[0]>5
0x40097c: jle 0x4009af
0x400982: call 0x400830 ;do_A
0x400987: movsx eax, byte ptr [rbp-17]
0x40098b: and eax, 15
0x400990: cmp eax, 7 ;x[1]<=7
0x400995: jnle 0x4009a5
0x40099b: call 0x400860 ;do_A1
0x4009a0: jmp 0x4009aa ;...
0x4009a5: call 0x400890 ;do_A2
0x4009af: call 0x4008c0 ;do_B
0x4009b4: movsx eax, byte ptr [rbp-17]
0x4009b8: and eax, 15
0x4009bd: cmp eax, 8 ;x[1]>8
0x4009c2: jle 0x4009d2
0x4009c8: call 0x4008f0 ;do_B1
0x4009d2: call 0x400920 ;do_B2
```

```
m = get_msg();
if (m[0] > 5)
    do_A();
    if (m[1] <= 7) do_A1();
    else do_A2();
else
    do_B();
    if (m[1] > 8) do_B1();
    else do_B2();
...
```

**input:** `m = byte ptr [rbp-17]`  
**branches:**  
{0x40097c, 0x400995, 0x4009c2}  
**checkpoints:**  
 $C_{0x40097c} = 0x400970$ ,  
 $C_{0x400995} = 0x400987$ ,  
 $C_{0x4009c2} = 0x4009b4$

**Implementation**

Ongoing work: a new approach in malware detection

Program similarity

FA approximation

Conclusions

# Fuzz testing optimization

- ▶ **naive approach** (infeasible):
  - ▶ e.g. a (compressed) DNS response message of size 79 bytes, has  $2^{79 \times 8}$  possible values!!!
  - ▶ re-executing the whole program for each test is expensive.
- ▶ **our approach: reverse execution and**
  - ▶ reduce the number of tested inputs,
  - ▶ reduce the length of re-execution traces: checkpoints by the **dynamic tainting analysis**.

# Dynamic tainting analysis by the liveness dataflow graph

From the executed trace  $t$ , construct a graph with **edges** are instructions, and for each edge

- ▶ **source nodes:** read operands,
- ▶ **target nodes:** written operands.

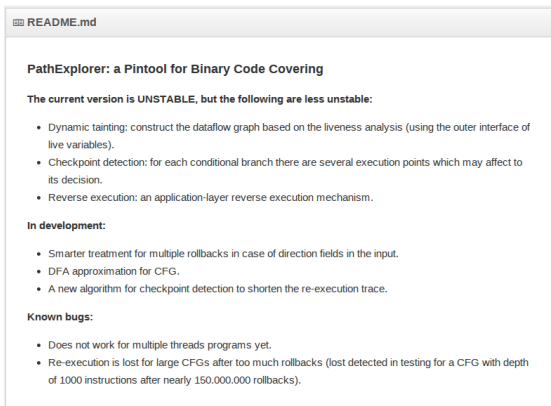

```
...  
movzx edi, word ptr [11]  
cmp word ptr [rax], di  
jz 0x35c360b7d8  
...
```

Taint propagation from the input message

# PathExplorer: a code covering tool

- ▶ using Pin **dynamic binary instrumentation** framework [2],
- ▶ source codes available at <https://github.com/tathanhdinh/PathExplorer>.

README.md

## PathExplorer: a Pintool for Binary Code Covering

The current version is UNSTABLE, but the following are less unstable:

- Dynamic tainting: construct the dataflow graph based on the liveness analysis (using the outer interface of live variables).
- Checkpoint detection: for each conditional branch there are several execution points which may affect to its decision.
- Reverse execution: an application-layer reverse execution mechanism.

In development:

- Smarter treatment for multiple rollbacks in case of direction fields in the input.
- DFA approximation for CFG.
- A new algorithm for checkpoint detection to shorten the re-execution trace.

Known bugs:

- Does not work for multiple threads programs yet.
- Re-execution is lost for large CFGs after too much rollbacks (lost detected in testing for a CFG with depth of 1000 instructions after nearly 150.000.000 rollbacks).

# Experiment

## Backtracking traversal on the CFG of wget

---

```
pin -t path_explorer.pin -r mlr -l depth -- wget url
```

---

### Options:

- ▶ mlr: the number of rollbacks for each checkpoint,
- ▶ depth: the depth of backtracking traversal.

depth	mlr	resolv/detected branches	total rollbacks
700	7000	4/7	21017
700	35000	8/12	169923
800	7000	19/54	301976
800	35000	40/97	2659205

Conclusions

# Malware characterization by message analysis

In malware detection, we look for **similarities** between a known malicious program  $M$  and a suspicious  $P$ .

- ▶ Traditional approach: **trace similarity**

# Malware characterization by message analysis

## Thesis

Two equivalent programs will interpret the input messages equivalently.

In malware detection, we look for **similarities** between a known malicious program  $M$  and a suspicious  $P$ .

- ▶ Traditional approach: **trace similarity**
- ▶ Our approach: **message interpretation similarity**
  - ▶ compare message relations instead of traces.

# Program similarity

## Input messages partition

Let  $\approx_{\mathcal{T}}$  be an equivalence between traces (e.g. partial similarity, control flow graph similarity, etc), the **derived equivalence**  $\approx_I$  between input messages is defined by:

$$i_1 \approx_I i_2 \iff P(i_1) \approx_{\mathcal{T}} P(i_2)$$

## Program similarity by input messages partition

$P \sim Q \iff$  having the same derived equivalence  $\approx_I$

**FA approximation**

Conclusions

# Input space partition by FA approximation

## Finite State Automata approximation

The input message space are partitioned by Finite State Automata

- ▶ The **input strings** are the inputs of the program,
- ▶ The **transition traces** abstract the execution traces.

That extends the current approach in the Protocol Message Extraction (Caballero et al. 2009).

## Corollary (systematic input format extraction)

*The precisely obtained FA reveals the format of inputs.*

## Early results in FA approximation

- ▶  $\{...\}$ : the parts of the input affecting to the branch's decision
- ▶ 0, 1: the decisions of a branch,
- ▶  $\perp$ : the execution halts before reaching the limit depth,
- ▶  $\llcorner$ : the execution continues after reaching the limit depth.

Figure: wget and ping have the same approximation at the depth 600

Program similarity

FA approximation

Conclusions

# Conclusions

- ▶ **Smart input fuzzing:** hybrid approach for the program covering
  - ▶ Dynamic-analysis: runs the program with a concrete input to get an execution trace,
  - ▶ Static-analysis: construct the dataflow graph on the trace to detect checkpoints.
  - ▶ Improvement in progress: symbolic execution with SMT solver.
- ▶ **Message analysis:** new approach for the program similarity
  - ▶ Similarity: relations between traces (instead of traces) are compared,
  - ▶ Protocol message extraction: the precisely obtained FA reveals the format of inputs.

## Conclusions (a brief comparison)

	current approaches	our approach
analysis method	hybrid	hybrid
covering purpose	functionality	trace
branch resolving technique	symbolic execution	fuzzing+re-execution trace minimization
rollbacking technique	whole-system emulation	application-wide reverse execution
source code	unknown	available
